In a system of N exchangeable interacting particles, as N increases, two particles become more and more statistically independent.

Mark Kac introduced the terminology *Propagation of chaos* to describe this phenomenon.

There is of course a huge litterature : Sznitman, Méléard, ... to the more recent by Malrieu, Mouhot, Mischler, Hauray, Delarue, Tse, Szpruch, Lacker, Jabin, Wang, Delgadino, Carrillo, Pavliotis....

Propagation of chaos

In a system of N interacting particles, as N increases, two particles become more and more statistically independent.

To quantify this "more and more", we compare the law of any subset of k particles within the N particles system to the law of k independent non-linear particles.

We will add the difficulty that we want uniform in time control !

The distance we will use to compare these laws will induce a strategy of proof :

- Wasserstein distance leads to coupling (Sznitman, Malrieu, ...)
- Energy/Entropy leads to more analytical proofs (with functional inequalities !) (Carrillo, Mc Cann, Villani, Mouhot, Mischler, Tugaut, Fournier, Jabin, Wang, Lacker, Delgadino, Carrillo, ...)
- weak norm and Lions derivatives calculus (Chassagneux, Szpruch, Tse, Delarue, Schlichting ...)

Introduction

Motivation

Propagation of chaos

Coupling approach

Analytical approach Results Step one Step two Step three Step four Step five On the assumpt

to do...

We denote, for any $k \leq N$

$$\rho_t^{k,N}(x_1,..,x_k) = \int_{\mathbb{T}^{(N-k)d}} \rho_t^N(x_1,..,x_N) dx_{k+1}...dx_N$$
$$\bar{\rho}_t^k = \bar{\rho}_t^{\otimes k}$$

Definition

Let μ and ν be two probability measures. We consider the Wasserstein distance for $\pmb{p} \in [1,2]$

$$W^p_p(
u,\mu) := \inf_{X \sim
u, Y \sim \mu} \mathbb{E}(|X - Y|^p)$$

Definition

Let μ and ν be two probability measures. We consider the rescaled relative entropy

$$\mathcal{H}_{N}(\nu,\mu) = \begin{cases} \frac{1}{N} \mathbb{E}_{\mu} \left(\frac{d\nu}{d\mu} \log \frac{d\nu}{d\mu} \right) & \text{if } \nu \ll \mu, \\ +\infty & \text{otherwise.} \end{cases}$$

Coupling approach

Introduction

Propagation of chao

Coupling approach

Analytical approach

Results Step one Step two Step three Step four Step five On the assumption to do...

Non convex case

Here we consider

$$dX_t^i = \sqrt{2}dB_t^i - \nabla V(X_t^i)dt - \frac{1}{N}\sum_j \nabla W(X_t^i - X_t^j)dt$$

with for example

- $V(x) = |x|^2$ and W convex
- $V(x) = |x|^4 |x|^2$ and $W(x) = \delta |x|^2$.

The uniformly strictly convex case (and even degenerately strictly convex) is done via **synchronuous coupling** : use the same Brownian motion for the linear and non linear particles system

$$dar{X}_t^i = \sqrt{2} dB_t^i -
abla V(ar{X}_t^i) dt -
abla W *
ho_t(ar{X}_t^i) dt$$

Introduction

Motivation Propagation of chaos

Coupling approach

Analytical approach

Results Step one Step two Step three Step four Step five On the assu to do...

$$\begin{aligned} d|X_t^i - d\bar{X}_t^j|^2 &= -2(X_t^i - \bar{X}_t^j) \cdot (\nabla V(X_t^i) - \nabla V(\bar{X}_t^j)) dt \\ &- \frac{2}{N} (X_t^i - \bar{X}_t^i) \sum_j (\nabla W(X_t^i - X_t^j) - \nabla W * \rho_t(\bar{X}_t^j)) dt \\ &= 2(X_t^j - \bar{X}_t^j) \cdot (\nabla V(X_t^j) - \nabla V(\bar{X}_t^j) d) t \\ &- \frac{2}{N} (X_t^i - \bar{X}_t^j) \sum_j (\nabla W(X_t^i - X_t^j) - \nabla W(\bar{X}_t^j - \bar{X}_t^j)) dt \\ &- \frac{2}{N} (X_t^j - \bar{X}_t^j) \sum_j (\nabla W(\bar{X}_t^i - \bar{X}_t^j) - \nabla W * \rho_t(\bar{X}_t^j)) dt. \end{aligned}$$

After summing : use convexity for the first term, smallness of δ and Lipschizianity for the second one, moment control and law of large numbers for the last one ! Conclude by Gronwall's lemma so that

$$\sup_{t\geq 0} W_2^2(\rho_t^{1,N},\bar{\rho}_t)\leq \frac{C}{N}.$$

Introduction

Propagation of chaos

Coupling approach

Analytical approach

Results Step one Step two Step three Step four Step five On the assumptio to do... The non convex case is trickier : synchronuous coupling does not help where you loose convexity...

One has to do reflection coupling : dB_t^i are replaced by

$$\left(I_d-2(\bar{X}_t^i-X_t^i)(\bar{X}_t^i-X_t^i)^T/\|\bar{X}_t^i-X_t^i\|^2\right)dB_t^i$$

but

 you cannot work with W₂! and even W₁ : necessary that we have a concave function of the distance for Itô's formula to help

$$W_{l^1,l}(
u,\mu) := \inf_{X \sim
u, Y \sim \mu} \mathbb{E} \frac{1}{N} \sum_{Y} f(|X^i - Y^i|),$$

• put the reflection coupling on the linear particles in order to use again the LLN for the non linear particles !

• do tedious calculations for the choice of the concave function *f* At the end :

$$\sup_{t\geq 0} W_1(\rho_t^{1,N},\bar{\rho}_t)\leq \frac{C}{\sqrt{N}}.$$

Introduction

Propagation of chaos

Coupling approach

Analytical approach

Results Step one Step two Step three Step four Step five

On the assumptions to do...

- 1 does not need the confinement and interaction to be gradient
- constructive but... perturbative (difficult to use interaction for uniformity in time)
- 3 extends to kinetic type models (Vlasov-Fokker-Planck equation)
- for singular models... yes, for Dyson's Brownian motion (see recent work by G-Le Bris-Monmarché)
- 6 kinetic singular?

Analytical approach

Results

Step one

Step two

Step thre

Step four

Step five On the assumption

to do...

Step two : Integration by part

We are left with

$$egin{aligned} rac{d}{dt}\mathcal{H}_{N}(t) &\leq -\mathcal{I}_{N}(t) \ &-rac{1}{N^{2}}\sum_{i,j}\int_{\mathbb{T}^{dN}}
ho_{t}^{N}\left(K(x_{i}-x_{j})-K*
ho(x_{i})
ight)\cdot
abla_{x_{i}}\logar{
ho}_{t}^{N}d\mathbf{X}^{N}. \end{aligned}$$

Idea : Use the regularity of $\bar{\rho}$ to deal with the singularity of K

Step two

Step four

to do ..

Step two : Integration by part

We are left with

0

$$egin{aligned} &rac{d}{dt}\mathcal{H}_N(t)\leq -\,\mathcal{I}_N(t)\ &-rac{1}{N^2}\sum_{i,j}\int_{\mathbb{T}^{dN}}
ho_t^N\left(\mathcal{K}(x_i-x_j)-\mathcal{K}*
ho(x_i)
ight)\cdot
abla_{x_i}\logar
ho_t^Nd\mathbf{X}^N. \end{aligned}$$

Idea : Use the regularity of $\bar{\rho}$ to deal with the singularity of K **Remark :** Notice that, for the Biot-Savart kernel on the whole space \mathbb{R}^2

$$\tilde{K}(x)=\frac{1}{2\pi}\frac{x^{\perp}}{|x|^2},$$

we have $\tilde{K} = \nabla \cdot \tilde{V}$ with

$$ilde{V}(x) = rac{1}{2\pi} \left(egin{array}{c} -\arctan\left(rac{x_1}{x_2}
ight) & 0 \ 0 & \arctan\left(rac{x_2}{x_1}
ight) \end{array}
ight).$$

Goal :
$$K(x) = rac{1}{2\pi} rac{x^{\perp}}{|x|^2} = rac{1}{2\pi} \left(-rac{x_2}{|x|^2}, rac{x_1}{|x|^2}
ight)$$

Justifying the calculations

- There is $\lambda > 1$ such that $\bar{\rho}_0 \in \mathcal{C}^{\infty}_{\lambda}(\mathbb{T}^d)$ $\implies \bar{\rho} \in \mathcal{C}^{\infty}_{\lambda}(\mathbb{R}^+ \times \mathbb{T}^d)$ (Ben-Artzi '94)
- $\rho^{\mathsf{N}} \in \mathcal{C}^{\infty}_{\lambda}(\mathbb{R}^+ \times \mathbb{T}^{\mathsf{Nd}})$ (???)

Dealing with the terms

- In the sense of distributions, $\nabla \cdot K = 0$.
- There is a matrix field $V \in L^{\infty}$ such that $K = \nabla \cdot V$, i.e for $1 \leq \alpha \leq d$, $K_{\alpha} = \sum_{\beta=1}^{d} \partial_{\beta} V_{\alpha,\beta}$ (Phuc-Torres '08).

Large deviation estimates -2

Theorem (Jabin-Wang '18)

Consider any probability measure μ on \mathbb{T}^d and $\phi \in L^{\infty}(\mathbb{T}^d \times \mathbb{T}^d)$ with

$$\gamma := \left(1600^2 + 36e^4\right) \left(\sup_{p \ge 1} \frac{\|\sup_z |\phi(\cdot, z)|\|_{L^p(\mu))}}{p}\right)^2 < 1.$$

Assume that ϕ satisfies the following cancellations

$$\forall z \in \mathbb{T}^d, \quad \int_{\mathbb{T}^d} \phi(x, z) \mu(dx) = 0 = \int_{\mathbb{T}^d} \phi(z, x) \mu(dx).$$

Then, for all $N \in \mathbb{N}$,

$$\int_{\mathbb{T}^{dN}} \exp\Big(\frac{1}{N}\sum_{i,j=1}^{N}\phi(x_i,x_j)\Big)\mu^{\otimes N}d\boldsymbol{X}^N \leq \frac{2}{1-\gamma} < \infty.$$
